

## Comment on Deploy

The device is provided in a Docker Image and should be deployed locally or within the local network to reduce latency between the data sent and the classification result collection. Depending on the client's currently available data pipeline, further deployment improvements may be completed using different technologies for the API, transitioning from REST APIs to more speed-oriented protocols. For example, in the case of an already existing pub/sub system, the app may be a sub and automatically classify each data published by the data distribution service.
